Abstract

In this paper, we present a model order reduction approach for nonlinear circuit equations with a small number of nonlinear elements. This approach is based on the decoupling of linear and nonlinear subcircuits and reducing the linear part using balancing-related model reduction techniques. The efficiency and applicability of the proposed model reduction approach is demonstrated on numerical examples.

Keywords: differential-algebraic equations, electronic circuits, modified nodal analysis, model reduction, balanced truncation, index

1 Introduction

The efficient and robust numerical simulation of integrated circuits plays a major role in computer-aided chip design. While the structural size of electronic devices is decreasing, their complexity is ever increasing. The mathematical modeling of such circuits leads to nonlinear systems of differential-algebraic equations (DAEs) containing up to millions or even more unknowns. Simulation of such large systems is mostly impossible or, at least, unacceptably time and storage consuming. Model order reduction provides a way out of this problem. A general idea of model reduction is to replace a large-scale system by a much smaller model which approximates the input-output relation of the original system within a required accuracy.

While a large variety of model reduction techniques such as PRIMA [13], SPRIM [6, 7] and PABTEC [17] exists for linear networks, model reduction of nonlinear circuits is only in its...
infancy [14, 19, 20, 23]. Typically, integrated circuits contain huge linear subnetworks modeling interconnects. A standard approach for model reduction of such nonlinear systems is to extract linear subsystems and replace them by reduced-order models, e.g., [5, 9, 13]. Then combining these reduced-order linear models with unchanged nonlinear components, one obtains a reduced-order nonlinear model that approximates the original system. The concept of this model reduction approach is presented in Figure 1. Although this approach is widely used in practice, only a little attention has been paid to approximation quality and properties of reduced-order nonlinear models.

![Image](image)

**Figure 1:** Model order reduction strategy for nonlinear circuits

In [9], model reduction based on partitioning linear and nonlinear subnetworks for a special class of RLC circuits with only nonlinear resistors has been considered and global error bounds have been presented. In this paper, we consider model reduction of more general circuits that may contain other nonlinear elements like nonlinear capacitors, inductors and transistors. We restrict ourself to circuits with a small number of nonlinear components. In this case, the extracted linear subcircuits have a small number of terminals, and they can be reduced by any known linear model reduction method. The separation of linear subnetworks from circuits containing many nonlinear elements will result in linear models with many inputs. For such systems, model order reduction can be combined with terminal reduction, e.g., [1, 4, 12].

The extraction of linear subsystems from a DAE system may lead to many unexpected effects such as index jump in the decoupled DAE subsystems or loss of regularity of the linear subsystem. This may then result in numerical instabilities, poor approximation and even failure of model reduction and simulation tools. In this paper, we develop a topology-based decoupling technique that avoids the increasing of the index and guarantees the
well-posedness of decoupled linear subsystems.

Another important issue in model reduction of electronic circuits via partitioning is the preservation of passivity and reciprocity in the reduced-order submodels. An interconnection of passive models is again passive meaning that the interconnected system does not generate energy [22]. Furthermore, passive and reciprocal systems can be realized as electrical circuits in a netlist format [10, 15, 25] that allows their transient analysis with standard circuit simulators. Therefore, for model reduction of linear subnetworks, we will use the passivity-preserving balanced truncation methods developed especially for electrical circuits in [17, 18]. An advantage of these methods over Krylov-type model reduction techniques is that they provide computable error bounds which can be used to estimate the approximation error for the reduced-order nonlinear system.

The paper is organized as follows. In Section 2, we briefly discuss the modeling of electrical circuits using the modified nodal analysis and present the circuit equations to be considered. In Section 3, we present a model reduction technique for nonlinear circuits based on partitioning linear and nonlinear subcircuits followed by reduction of the linear part. We also propose a decoupling strategy exploiting the topological structure of the circuit and investigate the properties of the decoupled systems. In Section 4, the efficiency of the proposed model reduction approach is demonstrated on numerical examples.

2 Circuit equations

A commonly used modeling tool for electrical circuits is the Modified Nodal Analysis (MNA) [24]. A circuit can be modeled as a directed graph whose edges correspond to the circuit elements like capacitors, resistors, inductors, and transistors and whose nodes correspond to the interconnections of these elements. The topological structure of such a graph with \(n_n + 1\) nodes and \(n_e\) edges can be described by an incidence matrix \(A_0 \in \{-1, 0, 1\}^{n_n+1,n_e}\) which has entries \(a_{ij} = 0, -1\) and 1 depending on whether edge \(j\) is incident with node \(i\) and whether this edge leaves or enters node \(i\). Using Kirchhoff’s current and voltage laws as well as the branch constitutive relations, the dynamics of the circuit can be described by a DAE system of the form

\[
\begin{align}
\mathcal{E}(x) \frac{d}{dt}x &= Ax + f(x) + Bu, \\
y &= B^Tx,
\end{align}
\]

(1a)

where \(x^T = [\eta^T \ i_L^T \ i_q^T] \), \(u^T = [u_L^T \ u_q^T]\) and \(y^T = [-u_q^T \ -i_q^T]\) are the state vector, input and output, respectively, and

\[
\mathcal{E}(x) = \begin{bmatrix}
A_{L}C(A_{C}^T \eta)A_{C}^T & 0 & 0 \\
0 & L(i_L) & 0 \\
0 & 0 & 0
\end{bmatrix}, \quad \mathcal{A} = \begin{bmatrix}
0 & -A_{L} & -A_{q} \\
A_{C}^T & 0 & 0 \\
A_{q} & 0 & 0
\end{bmatrix},
\]

(1c)

\[
f(x) = \begin{bmatrix}
-A_{R}g(A_{R}^T \eta) \\
0 \\
0
\end{bmatrix}, \quad B = \begin{bmatrix}
-A_{R} & 0 \\
0 & 0 \\
0 & -I
\end{bmatrix}.
\]

(1d)
In these model equations, $\eta$ is the vector of node potentials, $i_L$, $i_\nu$ and $u_\nu$ are the vectors of currents through inductors, voltage sources and current sources, respectively. $u_\nu'$ and $u_\eta$ are the vectors of voltages of voltage sources and current sources, respectively. The matrices $A_C \in \mathbb{R}^{n_C,m_C}$, $A_L \in \mathbb{R}^{n_L,m_L}$, $A_R \in \mathbb{R}^{n_R,m_R}$, $A_{\nu'} \in \mathbb{R}^{n_{\nu'},m_{\nu'}}$ and $A_\eta \in \mathbb{R}^{n_{\eta},m_{\eta}}$ are the incidence matrices describing the topology of the corresponding circuit elements, where the subscripts $C$, $L$, $R$, $\nu$ and $\eta$ stand for capacitors, inductors, resistors, voltage and current sources, respectively. Note that $A = \begin{bmatrix} A_C & A_L & A_R & A_{\nu'} & A_\eta \end{bmatrix}$ is a reduced incidence matrix obtained from $A_0$ by removing a row corresponding to a ground node. Furthermore, the capacitance matrix-valued function $C : \mathbb{R}^{n_C} \to \mathbb{R}^{n_C,n_C}$, the inductance matrix-valued function $L : \mathbb{R}^{n_L} \to \mathbb{R}^{n_L,n_L}$ and the resistor relation $g : \mathbb{R}^{n_R} \to \mathbb{R}^{n_R}$ characterize the physical properties of the capacitors, inductors and resistors, respectively. The state vector has the dimension $n = n_\eta + n_L + n_{\nu'}$, while the input and output vectors have the dimension $m = n_\eta + n_{\nu'}$.

We will assume that the DAE system (1) is well-posed in the sense that

(A1) the matrix $A_{\nu'}$ has full column rank,

(A2) the matrix $\begin{bmatrix} A_C & A_L & A_R & A_{\nu'} \end{bmatrix}$ has full row rank,

(A3) the matrices $C(A_C^T \eta)$ and $L(i_L)$ are symmetric, positive definite for all admissible $\eta$ and $i_L$,

(A4) the function $g(A_{\nu'}^T \eta)$ is monotonically increasing for all admissible $\eta$.

Assumptions (A1) and (A2) imply that the circuit does not contain loops of voltage sources and cutsets of current sources, respectively, while assumptions (A3) and (A4) mean that all circuit elements are passive, i.e., they do not generate energy.

In the following, we will distinguish between linear circuit elements like linear resistors, capacitors and inductors, and nonlinear circuit elements like nonlinear capacitors, inductors, diodes and transistors. A circuit element is called linear if the current-voltage relation for this element is linear. Otherwise, the circuit element is called nonlinear. Without loss of generality we assume that the circuit elements are ordered such that the incidence matrices can be partitioned as

$$A_C = \begin{bmatrix} A_{\tilde{C}} & A_{\bar{C}} \end{bmatrix}, \quad A_L = \begin{bmatrix} A_{\tilde{L}} & A_{\bar{L}} \end{bmatrix}, \quad A_R = \begin{bmatrix} A_{\tilde{R}} & A_{\bar{R}} \end{bmatrix},$$

(1e)

where the incidence matrices $A_{\tilde{C}}$, $A_{\tilde{L}}$ and $A_{\tilde{R}}$ correspond to the linear circuit components, and $A_{\bar{C}}$, $A_{\bar{L}}$ and $A_{\bar{R}}$ are the incidence matrices for the nonlinear devices. We also assume that the linear and nonlinear elements are not mutually connected, i.e.,

$$C(A_C^T \eta) = \begin{bmatrix} \tilde{C} & 0 \\ 0 & \bar{C}(A_C^T \eta) \end{bmatrix}, \quad L(i_L) = \begin{bmatrix} \tilde{L} & 0 \\ 0 & \bar{L}(i_{\bar{L}}) \end{bmatrix}, \quad g(A_{\eta}^T \eta) = \begin{bmatrix} \tilde{g} & 0 \\ 0 & \bar{g}(A_{\eta}^T \eta) \end{bmatrix},$$

(1f)

where $\tilde{C} \in \mathbb{R}^{n_{\tilde{C}},n_{\tilde{C}}}$, $\tilde{L} \in \mathbb{R}^{n_{\tilde{L}},n_{\tilde{L}}}$ and $\tilde{g} \in \mathbb{R}^{n_{\tilde{g}},n_{\tilde{g}}}$ are the capacitance, inductance and resistance matrices for the corresponding linear elements, whereas $\bar{C} : \mathbb{R}^{n_{\bar{C}}} \to \mathbb{R}^{n_{\bar{C}},n_{\bar{C}}}$,
\[ \bar{L}: \mathbb{R}^{n_c} \to \mathbb{R}^{n_c; n_c} \text{ and } \bar{g}: \mathbb{R}^{n_c} \to \mathbb{R}^{n_c} \text{ describe the corresponding nonlinear components, and} \]

\[ \bar{\iota}: \mathbb{R}^{n_c} \to \mathbb{R}^{n_c; n_c} \text{ is the vector of currents through the nonlinear inductors. It follows from assumptions} \]

\[ (A3) \text{ and } (A4) \text{ that the matrices } \bar{C}, \bar{L} \text{ and } \bar{g} \text{ are symmetric and positive definite; } \]

\[ \bar{C}^T \eta, \bar{L} (\bar{\iota}) \text{ and } \bar{g} (\bar{I}, \bar{\iota}) \text{ are symmetric and positive definite for all admissible } \eta \text{ and } \bar{\iota}, \text{ and } \bar{g} (\bar{I}, \bar{\iota}) \text{ is} \]

monotonically increasing for all admissible \( \eta \).

The index concept plays an important role in the analysis of DAEs. To characterize different analytical and numerical properties of DAE systems, several index notations have been introduced in the literature, e.g., [2, 8, 11]. For example, the differentiation index is roughly defined as the minimum of times that all or part of a DAE system must be differentiated with respect to \( t \) in order to determine the derivative of \( x \) as a continuous function of \( t \) and \( x \). In the following we will use the shorter term “index” instead of “differentiation index”.

It has been shown in [3] that the MNA system (1) satisfying assumptions (A1)-(A4) has index at most two. The index is zero if and only if \( n_q = 0 \text{ and } \text{rank}(A_c) = n_q \text{. The following lemma gives equivalent conditions for the circuit to be of index one.} \]

**Lemma 2.1** Consider a MNA system (1) that satisfies assumptions (A1)-(A4). Let \( Q_c \text{ be a projector onto ker } A_c^T \text{. The following conditions are equivalent:} \]

1. System (1) is of index one;
2. \( \text{rank}(Q_c^T A_q) = n_q \text{ and rank}([ A_c \ A_{\mathbb{R}} \ A_{q'} ]) = n_q; \)
3. \( \text{rank}([ A_c \ A_{q'} ]) = \text{rank}(A_c) + n_q \text{ and rank}([ A_c \ A_R \ A_{q'} ]) = n_q. \)

**Proof.** The equivalence of (i) and (ii) was proved in [3]. We now show that the conditions in (ii) and (iii) are equivalent. Obviously, it is enough to prove that \( \text{rank}(Q_c^T A_q) = n_q \text{ if and only if } \text{rank}([ A_c \ A_{q'} ]) = \text{rank}(A_c) + n_q. \)

Let \( S = [ S_1 \ S_2 ] \) be a nonsingular matrix such that the columns of \( S_2 \) form a basis of the kernel of \( A_c^T \), i.e., \( S_2^T A_c = 0 \). Then the projector \( Q_c \) can be represented as

\[ Q_c = S \left[ \begin{array}{cc} 0 & 0 \\ 0 & I \end{array} \right] S^{-1}. \]

We have \( \text{rank}(S_1^T A_c) = \text{rank}(S_1^T A_c) = \text{rank}(A_c) \text{ and } \text{rank}(S_2^T A_{q'}) = \text{rank}(Q_c^T A_{q'}). \)

Therefore,

\[ \text{rank}([ A_c \ A_{q'} ]) = \text{rank} \left[ \begin{array}{cc} S_1^T A_c & S_2^T A_{q'} \\ 0 & S_2^T A_{q'} \end{array} \right] = \text{rank}(A_c) + \text{rank}(Q_c^T A_{q'}). \]

Thus, the conditions \( \text{rank}(Q_c^T A_{q'}) = n_q \text{ and } \text{rank}([ A_c \ A_{q'} ]) = \text{rank}(A_c) + n_q \) are equivalent. \(\)

**Remark 2.2** Considering the topological structure of the circuit, the rank conditions in Lemma 2.1 imply that the circuit contains neither CV-loops (loops consisting of capacitors and/or voltage sources) except for C-loops (loops consisting of capacitors only) nor LI-cutsets (cutsets consisting of inductors and/or current sources). \[\]
3 Model reduction for nonlinear circuits

In this section, we present a model reduction approach for nonlinear circuits. The first step involves decoupling the nonlinear equations (1) into linear and nonlinear subsystems in a suitable way. Then the linear part is approximated by a reduced-order model of much smaller state space dimension using the FABTEC algorithm [17]. Combining this reduced-order linear model with the unchanged nonlinear subsystem, we obtain a nonlinear reduced-order model that approximates the original system (1). We now describe this model reduction procedure in more detail.

3.1 Decoupling of linear and nonlinear subcircuit

In preparation to the decoupling strategy, we first introduce some notation and present two auxiliary lemmata.

Lemma 3.1 Let \( G_1, G_2 \in \mathbb{R}^{n_x,n_x} \) be given such that \( G_1 + G_2 \) is invertible. Then the matrices

\[
\begin{align*}
\Gamma_{11} &= G_1(G_1 + G_2)^{-1}G_1, \\
\Gamma_{12} &= (G_1 + G_2)^{-1}G_1, \\
\Gamma_{21} &= G_2(G_1 + G_2)^{-1}G_1, \\
\Gamma_{22} &= G_2(G_1 + G_2)^{-1}G_2
\end{align*}
\]

satisfy the relations

\[
\Gamma_{12} = \Gamma_{21} = \Gamma_{11} = \Gamma_{22} = \Gamma_{21}.
\]

Proof. For \( \Gamma = G_1 + G_2 \), we have

\[
\Gamma_{12} = G_1\Gamma^{-1}(G_2 + G_1 - G_1) = G_1 - \Gamma_{11} = G_1 - (G_1 + G_2 - G_2)\Gamma^{-1}G_1 = \Gamma_{21}.
\]

Thus, the first two relations in (3) hold. The third relation in (3) can be proved analogously. □

Lemma 3.2 Let \( A^- \in \{-1,0,1\}^{n_y,n_x} \) and let the matrices \( G_1, G_2 \in \mathbb{R}^{n_x,n_x} \) be given such that \( \Gamma = G_1 + G_2 \) is invertible, and let \( \Gamma_{ij}, i,j = 1,2 \), be as in (2). Then we have the relation

\[
A^- \Gamma_{12} A^T_- = \begin{bmatrix} A^1_- & A^2_- \end{bmatrix} \begin{bmatrix} G_1 - \Gamma_{11} & \Gamma_{12} \\ \Gamma_{21} & G_2 - \Gamma_{22} \end{bmatrix} \begin{bmatrix} (A^1_-)^T \\ (A^2_-)^T \end{bmatrix},
\]

where \( A^1_- \in \{0,1\}^{n_y,n_x} \) and \( A^2_- \in \{-1,0\}^{n_y,n_x} \) satisfy \( A^1_- + A^2_- = A^- \).

Proof. For

\[
A^- = A^1_- + A^2_- = \begin{bmatrix} A^1_- & A^2_- \end{bmatrix} \begin{bmatrix} I \\ I \end{bmatrix},
\]
we get

\[ A_{\mathcal{R}} \Gamma_{12} A_{\mathcal{R}}^T = \begin{bmatrix} A_{\mathcal{R}}^1 & A_{\mathcal{R}}^2 \end{bmatrix} \begin{bmatrix} I \\ I \end{bmatrix} \Gamma_{12} \begin{bmatrix} I & I \\ \end{bmatrix} \begin{bmatrix} (A_{\mathcal{R}}^1)^T \\ (A_{\mathcal{R}}^2)^T \end{bmatrix}. \]

Then the statement follows from Lemma 3.1. \( \square \)

**Definition 3.3** Two DAE systems

\[ \mathcal{E}_1(x_1) \frac{d}{dt} x_1 = f_1(x_1) + B_1 u, \]
\[ y_1 = C_1 x_1 \]

and

\[ \mathcal{E}_2(x_2) \frac{d}{dt} x_2 = f_2(x_2) + B_2 u, \]
\[ y_2 = C_2 x_2 \]

with \( \mathcal{E}_j(x_j) \in \mathbb{R}^{n_j}, f_j(x_j) \in \mathbb{R}^n, B_j \in \mathbb{R}^{n_j \times m} \) and \( C_j \in \mathbb{R}^{n_j \times n}, j = 1, 2 \), are called state equivalent if for a given input \( u \), the solutions of these systems satisfy \( x_1 = \Pi x_2 \) with a permutation matrix \( \Pi \).

Our goal is now to extract a linear subcircuit from a nonlinear circuit. This can be achieved, for example, via the replacement of nonlinear circuit devices by controlled current sources. An advantage of this strategy is that no additional nodes and, hence, no additional states are introduced into the system. However, in this case, \( LL \)-cutsets may occur that may result in the increasing of the index. To avoid this, we replace the nonlinear capacitors and resistors by controlled voltage sources. Unfortunately, this introduce additional states into the DAE system. Furthermore, the replacement of the nonlinear resistors by voltage sources may lead to the appearance of \( CV \)-loops that may again increase the index of the extracted linear DAE system. To overcome this difficulty, we propose to replace the nonlinear resistors by an equivalent circuit consisting of two serial linear resistors and one controlled current source connected parallel to one of the resistors as shown in Figure 2. This introduces additional nodes, but neither additional \( CV \)-loops nor \( LL \)-cutsets occur in the decoupled subcircuit meaning that the index remains unchanged. The suggested replacements are exemplary demonstrated in Figure 3, where we present two circuits before and after replacements.

Note that all replacements described above and decoupling the linear subcircuit from the nonlinear circuit can easily be carried out on the netlist level. In the following theorem, we perform this decoupling on the equation level.
Figure 2: Replacements for nonlinear circuit elements

Figure 3: Exemplary replacements

Theorem 3.4 Let $A^1_R \in \{0, 1\}^{n_x n_x}$ and $A^2_R \in \{-1, 0\}^{n_x n_x}$ satisfy $A^1_R + A^2_R = A^n_R$, and let $G_1, G_2 \in \mathbb{R}^{n_x n_x}$ be given such that $G_1$, $G_2$ and $\Gamma = G_1 + G_2$ are symmetric, positive definite. Assume that $u_\tilde{C} \in \mathbb{R}^{n_x}$ and $i_z \in \mathbb{R}^{n_x}$ satisfy

$$u_\tilde{C} = A^T_\tilde{C} \eta,$$

$$i_z = \Gamma G^{-1}_1 g(A^T_\tilde{C} \eta) - G_2 A^T_\tilde{C} \eta.$$  

Then system (1) together with the relations

$$i_\tilde{C} = \tilde{C}(u_\tilde{C}) \frac{d}{dt} u_\tilde{C},$$

$$\eta_z = \Gamma^{-1} (G_1(A^1_R)^T \eta - G_2(A^2_R)^T \eta - i_z)$$
for the additional unknowns $\eta_{t} \in \mathbb{R}^{n_{c}}$ and $\zeta_{t} \in \mathbb{R}^{n_{c}}$ is state equivalent to the system

$$\bar{L} (\eta_{t}) \frac{d}{dt} \eta_{t} = A_{L}^{T} \eta$$

This coupled with the linear DAE system

$$E \frac{d}{dt} x_{t} = A x_{t} + B u_{t},$$

$$y_{t} = B^{T} x_{t},$$

where $x_{t}^{T} = [\eta_{t}^{T} \eta_{t}^{T} \zeta_{t}^{T} \zeta_{t}^{T} \zeta_{t}^{T} u_{t}^{T} u_{t}^{T}]$, $u_{t}^{T} = [v_{t}^{T} v_{t}^{T} v_{t}^{T} u_{t}^{T} u_{t}^{T}]$ and

$$E = \begin{bmatrix} A_{C} C A_{L}^{T} & 0 & 0 \\ 0 & L & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} -A_{R} G A_{R}^{T} & -A_{L} & -A_{V} \\ A_{L}^{T} & 0 & 0 \\ A_{V}^{T} & 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} -A_{I} & 0 \\ 0 & 0 \\ 0 & -I \end{bmatrix},$$

with $E, A \in \mathbb{R}^{n_{t},n_{t}}$, $B \in \mathbb{R}^{n_{t},n_{u}}$ and the incidence and element matrices

$$A_{C} = \begin{bmatrix} A_{\zeta} \\ 0 \end{bmatrix}, \quad A_{R} = \begin{bmatrix} A_{R}^{1} & A_{R}^{2} \\ A_{R}^{3} & I \end{bmatrix}, \quad A_{L} = \begin{bmatrix} A_{\zeta} \\ 0 \end{bmatrix},$$

$$A_{V} = \begin{bmatrix} A_{\psi} & A_{\zeta} \\ 0 & 0 \end{bmatrix}, \quad A_{I} = \begin{bmatrix} A_{\psi} & A_{\zeta} \\ 0 & I \end{bmatrix},$$

$$G = \begin{bmatrix} \hat{G} & 0 & 0 \\ 0 & G_{1} & 0 \\ 0 & 0 & G_{2} \end{bmatrix}, \quad C = \tilde{C}, \quad L = \bar{L}.$$  

**Proof.** We show that $[ x_{t}^{T} \eta_{t}^{T} \zeta_{t}^{T} \zeta_{t}^{T} u_{t}^{T} u_{t}^{T}]^{T}$ solves (1) and (5) if and only if $[ x_{t}^{T} \eta_{t}^{T} \zeta_{t}^{T} \zeta_{t}^{T} u_{t}^{T} u_{t}^{T}]^{T}$ solves (6) and (7). First note that these vectors are identical up to a permutation. Using (1f), (4a) and the voltage-current relation (5a) for the nonlinear capacitors, we can rewrite system (1a), (1c)-(1f) as

$$A_{\zeta} \tilde{C} A_{\zeta}^{T} \frac{d}{dt} \eta_{t} = -A_{\zeta} \tilde{G} A_{\zeta}^{T} \eta_{t} - A_{\zeta} \zeta_{t} \zeta_{\bar{L}} - A_{\psi} \psi_{t} - A_{\zeta} \psi_{\bar{L}} - A_{\zeta} \zeta_{t} \zeta_{\bar{L}} - A_{\zeta} g(A_{\zeta}^{T} \eta_{t}) - A_{\zeta} \zeta_{t} \zeta_{\bar{L}},$$

$$\bar{L} \frac{d}{dt} \eta_{t} = A_{L}^{T} \eta_{t},$$

$$\bar{L} (\eta_{t}) \frac{d}{dt} \zeta_{t} = A_{L}^{T} \eta_{t},$$

$$0 = A_{\psi}^{T} \eta_{t} - u_{\psi},$$

$$0 = A_{\zeta}^{T} \eta_{t} - u_{\zeta}.$$
It follows from (4b) that $\bar{g}(A^T_{\mathcal{R}} \eta) = G_1 \Gamma^{-1} \eta_z + \Gamma_{12} A^T_{\mathcal{R}} \eta$ with $\Gamma_{12}$ as in (2b). Substituting this $\bar{g}(A^T_{\mathcal{R}} \eta)$ in (8a) and inserting the relation (5b) for the variable vector $\eta_z$, we have

$$A_{\mathcal{C}} \tilde{C} A^T_{\mathcal{C}} \frac{d}{dt} \eta = -(A_{\mathcal{R}} \tilde{g} A^T_{\mathcal{R}} + A_{\mathcal{R}} \Gamma_{12} A^T_{\mathcal{R}}) \eta - A_{\tilde{L}}' \eta_z - A_{\tilde{L}}^T \eta - A_{\tilde{L}} + \tilde{c}^T \eta$$  \hspace{.5cm} (9a)

$$0 = \left(G_1 (A^T_{\mathcal{R}}) - G_2 (A^T_{\mathcal{R}}) \right) \eta - \Gamma \eta_z - \eta_z'$$  \hspace{.5cm} (9b)

$$\tilde{L} \frac{d}{dt} \tilde{L} = A^T_{\tilde{L}} \eta,$$  \hspace{.5cm} (9c)

$$\tilde{L} (t \tilde{L}) \frac{d}{dt} \tilde{L} = A^T_{\tilde{L}} \eta,$$  \hspace{.5cm} (9d)

$$0 = A_{\tilde{L}}' \eta - u_q,$$  \hspace{.5cm} (9e)

$$0 = A_{\tilde{L}}^T \eta - u_{\tilde{c}}.$$  \hspace{.5cm} (9f)

Finally, multiplying (9b) by $-(A^T_{\mathcal{R}} G_1 - A^T_{\mathcal{R}} G_2) \Gamma^{-1}$ and adding up the resulting equation to (9a), we obtain using Lemma 3.1 the system

$$A_{\mathcal{C}} \tilde{C} A^T_{\mathcal{C}} \frac{d}{dt} \eta = -(A_{\mathcal{R}} \tilde{g} A^T_{\mathcal{R}} + A_{\mathcal{R}} G_1 A^T_{\mathcal{R}} - A_{\mathcal{R}} G_2 A^T_{\mathcal{R}}) \eta$$  \hspace{.5cm} (10a)

$$+ (A_{\mathcal{R}} G_1 T - A_{\mathcal{R}} G_2 T) \eta_z - A_{\tilde{L}}' \eta_z - A_{\tilde{L}}^T \eta_z - A_{\tilde{L}} + \tilde{c}^T \eta$$  \hspace{.5cm} (10b)

$$0 = \left(G_1 (A^T_{\mathcal{R}}) - G_2 (A^T_{\mathcal{R}}) \right) \eta - \Gamma \eta_z - \eta_z'$$  \hspace{.5cm} (10c)

$$\tilde{L} \frac{d}{dt} \tilde{L} = A^T_{\tilde{L}} \eta,$$  \hspace{.5cm} (10d)

$$\tilde{L} (t \tilde{L}) \frac{d}{dt} \tilde{L} = A^T_{\tilde{L}} \eta,$$  \hspace{.5cm} (10e)

$$0 = A_{\tilde{L}}' \eta - u_q,$$  \hspace{.5cm} (10f)

$$0 = A_{\tilde{L}}^T \eta - u_{\tilde{c}}.$$  \hspace{.5cm} (10f)

Thus, equations (10), (1b) are state equivalent to the DAE system (6), (7). □

Note that the system matrices in the decoupled linear system (7) are in the MNA form with $A_{\mathcal{C}} \in \mathbb{R}^{n_\mathcal{C}, n_{\mathcal{C}}}$, $A_{\tilde{L}} \in \mathbb{R}^{n_{\tilde{L}}, n_{\tilde{L}}}$, $A_{\mathcal{R}} \in \mathbb{R}^{n_{\mathcal{R}}, n_{\mathcal{R}}}$, $A_{\mathcal{V}} \in \mathbb{R}^{n_{\mathcal{V}}, n_{\mathcal{V}}}$, $A_{\mathcal{F}} \in \mathbb{R}^{n_{\mathcal{F}}, n_{\mathcal{F}}}$ and $G \in \mathbb{R}^{n_{G}, n_{G}}$, $C \in \mathbb{R}^{n_{C}, n_{C}}$, $L \in \mathbb{R}^{n_{L}, n_{L}}$, where $n_{\tilde{L}} = n_{\eta} + n_{\mathcal{C}}$, $n_{\mathcal{C}} = n_{\tilde{L}}$, $n_{L} = n_{\mathcal{L}}$, $n_{\mathcal{R}} = n_{\mathcal{R}} + 2n_{\mathcal{C}}$, $n_{\mathcal{V}} = n_{\mathcal{G}} + n_{\mathcal{C}}$ and $n_{\mathcal{F}} = n_{\eta} + n_{\mathcal{L}} + n_{\mathcal{R}} + n_{\mathcal{C}}$. System (7) has the state space dimension $n_{\mathcal{C}} = n_{\eta} + n_{\mathcal{L}} + n_{\mathcal{V}}$ and the input space dimension $m_{\mathcal{F}} = n_{\eta} + n_{\mathcal{V}}$. It should also be noted that the state equivalence in Theorem 3.4 is independent of the choice of the matrices $G_1$ and $G_2$ satisfying the assumptions in the theorem. The substitution of nonlinear resistors with equivalent circuits as described above implies that these matrices are diagonal and their diagonal elements are conductances of the first and the second linear resistors, respectively, in the replacement circuits. The following example demonstrates that these conductances can indeed be chosen arbitrarily.

**Example 3.5** Consider a simple RCV circuit shown in Figure 4a. Such a circuit can be
described by the MNA equations in the form

\[
\begin{bmatrix}
\bar{C} & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\frac{d}{dt} \eta_1 \\
\frac{d}{dt} \eta_2 \\
\frac{d}{dt} \eta_3 \\
\end{bmatrix}
= \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & -1 & 0
\end{bmatrix}
\begin{bmatrix}
\eta_1 \\
\eta_2 \\
\eta_3
\end{bmatrix}
+ \begin{bmatrix}
\frac{-\bar{g}(\eta_1 - \eta_2)}{\bar{g}(\eta_1 - \eta_2)} \\
0
\end{bmatrix}
u_y + \begin{bmatrix}
0 \\
0 \\
-1
\end{bmatrix}u_y, \quad (11a)
\]

\[
y = \begin{bmatrix}
0 \\
0 \\
-1
\end{bmatrix}
\begin{bmatrix}
\eta_1 \\
\eta_2 \\
\eta_3
\end{bmatrix}. \quad (11b)
\]

The incidence matrices are given by

\[
A_{\bar{C}} = \begin{bmatrix}
1 \\
0
\end{bmatrix}, \quad A_{\bar{R}} = \begin{bmatrix}
1 \\
-1
\end{bmatrix}, \quad A_{\psi} = \begin{bmatrix}
0 \\
-1
\end{bmatrix},
\]

and, hence,

\[
A_{\bar{C}}^{-1}A_{\bar{R}} = \begin{bmatrix}
1 \\
1
\end{bmatrix}
\begin{bmatrix}
1 \\
-1
\end{bmatrix}
= \begin{bmatrix}
1 \\
0
\end{bmatrix}.
\]

According to the developed replacement strategy, we introduce the new node 3 with the potential \(\eta_3\), two linear resistors with conductances \(G_1\) and \(G_2\) and the current source

\[
\nu_z = \Gamma G_1^{-1}g(\eta_1 - \eta_2) - G_2(\eta_1 - \eta_2) \quad (12)
\]

with \(\Gamma = G_1 + G_2\). The new circuit is shown in Figure 4b. It is described by the MNA system

\[
\begin{bmatrix}
\bar{C} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\frac{d}{dt} \eta_1 \\
\frac{d}{dt} \eta_2 \\
\frac{d}{dt} \eta_3 \\
\frac{d}{dt} \eta_4
\end{bmatrix}
= \begin{bmatrix}
-G_1 & 0 & G_1 & 0 \\
0 & -G_2 & G_2 & 1 \\
G_1 & G_2 & -\Gamma & 0 \\
0 & -1 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\eta_1 \\
\eta_2 \\
\eta_3 \\
\eta_4
\end{bmatrix}
+ \begin{bmatrix}
0 \\
0 \\
1 \\
-1
\end{bmatrix}
\begin{bmatrix}
\nu_1 \\
\nu_2 \\
\nu_3 \\
\nu_4
\end{bmatrix}, \quad (13a)
\]

\[
y = \begin{bmatrix}
0 & 0 & -1 & 0 \\
0 & 0 & 0 & -1
\end{bmatrix}
\begin{bmatrix}
\eta_1 \\
\eta_2 \\
\eta_3 \\
\eta_4
\end{bmatrix}. \quad (13b)
\]
We now show that system (11a) together with the equation
\[ \eta_3 = \Gamma^{-1}(G_1 \eta_1 + G_2 \eta_2 - \xi_z) \] (14)
is equivalent to (13a) independent of the choice of \( G_1 \) and \( G_2 \). Indeed, the third equation in (13a) yields (14). Substituting \( \eta_3 \) in the first and the second equations in (13a) and taking into account (12), we obtain
\[
\begin{bmatrix}
\dot{C} & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\frac{d}{dt} \eta_1 \\
\frac{d}{dt} \eta_2 \\
\frac{d}{dt} \tilde{\eta}_4
\end{bmatrix}
= \begin{bmatrix}
-G_1 \eta_1 + G_1 \Gamma^{-1}(G_1 \eta_1 + G_2 \eta_2 - \xi_z) \\
-G_2 \eta_2 + G_2 \Gamma^{-1}(G_1 \eta_1 + G_2 \eta_2 - \xi_z) + \xi_z + \xi_{\tilde{\eta}_4} \\
-\tilde{y}(\eta_1 - \eta_2) + \xi_{\tilde{\eta}_4} \\
\eta_2 - \xi_{\tilde{\eta}_4}
\end{bmatrix}.
\]
The reverse statement can be proved analogously.

The following theorem establishes the well-posedness of the decoupled linear system (7) under conditions that the original circuit does not contain \( \tilde{C}V \)-loops (loops consisting of nonlinear resistors and/or voltage sources) and \( LL \)-cutsets (cutsets consisting of nonlinear inductors and/or current sources). \( \tilde{C}V \)-loops and \( LL \)-cutsets in the original circuit (1) would lead after the replacement of the nonlinear capacitors and nonlinear inductors by voltage sources and current sources, respectively, to \( V \)-loops and \( I \)-cutsets in the decoupled circuit (7) that would violate its well-posedness.

**Theorem 3.6** Let a nonlinear circuit satisfy assumptions (A1)-(A4). Additionally, assume that it contains neither \( \tilde{C}V \)-loops nor \( LL \)-cutsets. Then the linear DAE system (7) modeling the extracted linear subcircuit is well-posed in the sense that

1. the matrix \( A_V \) has full column rank;
2. the matrix \( \begin{bmatrix} A_C & A_L & A_R & A_V \end{bmatrix} \) has full row rank;
3. the matrices \( C, L \) and \( G \) are symmetric and positive definite.

**Proof.** The third property immediately follows from assumptions (A3), (A4) and the diagonal structure of \( G_1 \) and \( G_2 \). If the circuit does not contain \( \tilde{C}V \)-loops, then the matrix \( \begin{bmatrix} A_{\tilde{\eta}_4} & A_{\tilde{\eta}_3} \end{bmatrix} \) has full column rank. Hence, \( A_V \) in (7e) has also full column rank. The absence of \( LL \)-cutsets implies that the matrix \( \begin{bmatrix} A_{\tilde{\eta}_4} & A_{\tilde{\eta}_3} & A_{\tilde{\eta}_2} & A_{\tilde{\eta}_1} & A_V \end{bmatrix} \) has full row rank. Then it follows from
\[
\text{rank}(\begin{bmatrix} A_C & A_L & A_R & A_V \end{bmatrix}) = \text{rank}(\begin{bmatrix}
A_{\tilde{\eta}_4} & A_{\tilde{\eta}_3} & A_{\tilde{\eta}_2} & A_{\tilde{\eta}_1} & A_V \\
0 & 0 & 0 & -I & I \\
0 & 0 & 0 & I & 0 \\
0 & 0 & 0 & 0 & I
\end{bmatrix})
= \text{rank}(\begin{bmatrix}
A_{\tilde{\eta}_4} & A_{\tilde{\eta}_3} & A_{\tilde{\eta}_2} & A_{\tilde{\eta}_1} & A_V \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix})
\]

12
that the matrix \[ \begin{bmatrix} A_C & A_L & A_R & A_V \end{bmatrix} \] has also full row rank. \(\Box\)

We now show that the slightly stronger index one condition for the nonlinear circuit guarantees that the decoupled linear DAE system (7) is well-posed and, in addition, has index at most one.

**Theorem 3.7** Let a nonlinear circuit satisfy assumptions (A1)-(A4). If this circuit contains neither CV-loops except for \(\mathcal{C}\)-loops with linear capacitors nor LI-cutsets, then the linear DAE system (7) modeling the extracted linear subcircuit is well-posed and is of index at most one.

**Proof.** Since the circuit does not have LI-cutsets and CV-loops except for \(\mathcal{C}\)-loops, Theorem 3.6 implies that system (7) is well-posed. Moreover, from Remark 2.2 we have

\[
\text{rank}\left( \begin{bmatrix} A_{\hat{z}} & A_{\hat{\mathcal{C}}} & A_{q'} \end{bmatrix} \right) = \text{rank}(A_{\hat{z}}) + n_{\hat{z}} + n_{q'},
\]

\[
\text{rank}\left( \begin{bmatrix} A_{\hat{z}} & A_{\hat{\mathcal{C}}} & A_{\hat{\mathbb{R}}} & A_{q'} \end{bmatrix} \right) = n_\eta.
\]

Therefore,

\[
\text{rank}\left( \begin{bmatrix} A_C & A_V \end{bmatrix} \right) = \text{rank}\left( \begin{bmatrix} A_{\hat{z}} & A_{q'} \end{bmatrix} \right) = \text{rank}(A_{\hat{z}}) + (n_{q'} + n_{\hat{z}}) = \text{rank}(A_C) + n_V,
\]

\[
\text{rank}[A_C, A_R, A_V] = \text{rank}\left( \begin{bmatrix} A_{\hat{z}} & A_{\hat{\mathbb{R}}} & A_{q'} & 0 \\ 0 & 0 & 0 & 0 & I \end{bmatrix} \right) = n_\eta + n_{\hat{\mathbb{R}}} = n_\eta.
\]

Note that \(n_\eta = n_\eta + n_{\hat{\mathbb{R}}} \) is the number of nodes in (7). Thus, from Lemma 2.1 we get that the system (7) is of index at most one. \(\Box\)

Note that the index one condition for system (7) implies that its transfer function is proper, i.e., it is bounded at infinity. The approximation of such systems is much easier than that of systems with an improper transfer function [21].

### 3.2 Balancing-related model reduction of linear circuits

We now aim to approximate the decoupled linear DAE system (7) by a reduced-order model

\[
\begin{align*}
\dot{\hat{x}}_t + & \frac{\hat{A}}{\hat{C}} \hat{x}_t = \hat{B} u, \\
\hat{y}_t &= \hat{C} \hat{x}_t,
\end{align*}
\]

where \(\hat{E}, \hat{A} \in \mathbb{R}^{r_t, r_t}, \hat{B} \in \mathbb{R}^{r_t, m_u}, \hat{C} \in \mathbb{R}^{m_r, r_t},\) and \(r_t\) is much smaller than the state space dimension \(n_t\) of system (7). Such a model can be computed via the PABTEC algorithm [17] based on balanced truncation. In general, balanced truncation model reduction methods rely on the transformation of the dynamical system into a balanced form whose controllability and observability Gramians are both equal to a diagonal matrix. Then a reduced-order model is determined by the truncation of the states corresponding to small diagonal elements of the balanced Gramians. Depending on system properties, different types of
Gramians may be introduced. For passivity-preserving model reduction, the Gramians are defined as unique stabilizing solutions of the projected Riccati equations

\[
EX\ddot{X}^T + \dot{X} X E^T + EX \ddot{C}_r C^T X E + P_t \dot{B} \ddot{B}^T P_t = 0, \quad X = P_r X P_r^T, \quad (16)
\]

\[
E^T Y \ddot{A} + \dot{A} Y E^T + E^T Y \ddot{B} \ddot{B}^T Y E + P_r \ddot{C}_r \ddot{C}_r P_r = 0, \quad Y = P_r^T Y P_r, \quad (17)
\]

where

\[
\ddot{A} = A - BB^T - 2P_t B (I - M_0^T M_0)^{-1} M_0^T B^T P_r,
\]

\[
\ddot{B} = \sqrt{2} J_0^{-1} R_{x,1}^{-1}, \quad \ddot{C} = \sqrt{2} J_0^{-1} B^T,
\]

\[
J_0^T J_0 = I - M_0^T M_0, \quad J_0^T J_0^T = I - M_0 M_0^T,
\]

\[
M_0 = I - \lim_{s \to \infty} B^T (sE - A + BB^T)^{-1} B,
\]

and \(P_r\) and \(P_l\) are the spectral projectors onto the right and left deflecting subspaces of the pencil \((sE - (A - BB^T))\) corresponding to the finite eigenvalues.

Let \(R_x\) and \(R_y\) be the Cholesky factors of the Gramians \(X = R_x R_x^T\) and \(Y = R_y R_y^T\), respectively. Compute the singular value decomposition

\[
R_y^T ER_x = [U_1, U_2] \begin{bmatrix}
\Pi_1 & 0 \\
0 & \Pi_2
\end{bmatrix}[V_1, V_2]^T,
\]

where \([U_1, U_2]\) and \([V_1, V_2]\) have orthonormal columns,

\[
\Pi_1 = \text{diag}(\pi_1, \ldots, \pi_r), \quad \Pi_2 = \text{diag}(\pi_{r+1}, \ldots, \pi_q)
\]

with \(\pi_1 \geq \ldots \geq \pi_r > \pi_{r+1} \geq \ldots \geq \pi_q\). The values \(\pi_j\) are called the characteristic values of system (7). They determine the important state variables of the balanced system. The reduced-order model (15) can be computed by projection onto the left and right subspaces corresponding to the dominant characteristic values. Such a model is given by

\[
\hat{E} = \begin{bmatrix}
I_r & 0 \\
0 & 0
\end{bmatrix}, \quad \hat{A} = \frac{1}{2} \begin{bmatrix}
2 W^T A T & \sqrt{\frac{2}{\sqrt{2}}} W^T B C_{\infty} \\
-\sqrt{\frac{2}{\sqrt{2}}} B_{\infty} B^T T & 2 I - B_{\infty} C_{\infty}
\end{bmatrix},
\]

\[
\hat{B} = \begin{bmatrix}
W^T B \\
- B_{\infty}/\sqrt{2}
\end{bmatrix}, \quad \hat{C} = \begin{bmatrix}
B^T T & C_{\infty}/\sqrt{2}
\end{bmatrix},
\]

where \(W = L U_1 P_1^{-1/2}\), \(T = R Y V_1 P_1^{-1/2}\), and the matrices \(B_\infty\) and \(C_\infty\) are chosen such that \(I - M_0 = C_{\infty} B_\infty\). One can show that the reduced-order system (15), (18) is passive, reciprocal and its index does not exceed the index of (7), see [17]. Let

\[
G(s) = B^T (sE - A)^{-1} B, \quad \hat{G}(s) = \hat{C} (s \hat{E} - \hat{A})^{-1} \hat{B}
\]

be the transfer functions of systems (7) and (15), respectively. Then we can estimate the \(H_\infty\)-norm of the error defined as

\[
\|G - \hat{G}\|_{H_\infty} = \sup_{\omega \in \mathbb{R}} \|G(i\omega) - \hat{G}(i\omega)\|,
\]

14
where $\| \cdot \|$ denotes the spectral matrix norm. If $\| I + G \|_{\infty} (\pi_{r+1} + \ldots + \pi_q) < 2$, then we have the following error bound

$$\| G - G \|_{\infty} \leq 2\| I + G \|_{\infty}^2 (\pi_{r+1} + \ldots + \pi_q),$$

see [16]. In the time domain, the error in the output can be bounded as

$$\| \hat{y}_t - y_t \|_{2} \leq \| \hat{G} - G \|_{\infty} \| u \|_{2}.$$

By exploiting the structure of circuit equations, this model reduction procedure can be made more efficient and accurate. Since the MNA matrices in (7c) satisfy

$$E^T = S_{\text{int}} E S_{\text{int}}, \quad A^T = S_{\text{int}} A S_{\text{int}}, \quad B^T = S_{\text{ext}} B^T S_{\text{int}},$$

where $S_{\text{int}} = \text{diag}(I_{n_I}, -I_{n_L}, -I_{n_V})$ and $S_{\text{ext}} = \text{diag}(I_{n_I}, -I_{n_V})$, we find that

$$P_l = S_{\text{int}} P_l^T S_{\text{int}}, \quad Y_{\text{min}} = S_{\text{int}} Y_{\text{min}} S_{\text{int}} = S_{\text{int}} R_X R_X^T S_{\text{int}} = R_Y R_Y^T.$$  

Thus, for the linear circuit equations (7), it is enough to compute one projector and solve one projected Riccati equation only. Another projector and also the solution of the dual Riccati equation are given for free. Furthermore, we can show that $R_{l}^{1} E_{l} R_{X} = R_{l}^{2} S_{\text{int}} E_{l} R_{X}$ is symmetric. Then the characteristic values $\pi_j$ can be computed from an eigenvalue decomposition of $R_{l}^{2} S_{\text{int}} E_{l} R_{X}$ instead of a more expensive singular value decomposition. If $\lambda_j$ are eigenvalues of $R_{l}^{2} S_{\text{int}} E_{l} R_{X}$, then $\pi_j = |\lambda_j|$. Finally, using the symmetry of the matrix $(I - M_0)S_{\text{ext}}$, we can determine $B_{\infty}$ and $C_{\infty}$ from the eigenvalue decomposition of $(I - M_0)S_{\text{ext}}$. The resulting model reduction method is summarized in Algorithm 3.2.

Note that for RC and RL circuits, also the passivity-preserving balanced truncation model reduction approach based on projected Lyapunov equations [18] can be applied to compute the reduced-order model (15).

### 3.3 Reduced-order nonlinear circuit

We now apply the PABTEC method to the linear descriptor system (7). As a result we obtain a reduced-order model (15). In particular, this model has the form

$$\dot{E} \frac{d}{dt} \tilde{x}_t = \tilde{A} \tilde{x}_t + \begin{bmatrix} \tilde{B}_1 & \tilde{B}_2 & \tilde{B}_3 & \tilde{B}_4 & \tilde{B}_5 \end{bmatrix} \begin{bmatrix} \nu_j \\ \nu_z \\ \nu_L \\ \nu_{q'} \\ \nu_{\tilde{C}} \end{bmatrix},$$

$$\begin{bmatrix} \hat{y}_t \\ \hat{y}_{q2} \\ \hat{y}_{q3} \\ \hat{y}_{q4} \\ \hat{y}_{q5} \end{bmatrix} = \begin{bmatrix} \tilde{C}_1 \\ \tilde{C}_2 \\ \tilde{C}_3 \\ \tilde{C}_4 \\ \tilde{C}_5 \end{bmatrix} \tilde{x}_t,$$
\textbf{Algorithm 1} Passivity-preserving balanced truncation for electrical circuits (PABTEC).

Given \((E, A, B, B^T)\) as in (7c), compute a reduced-order model \((E, A, B, C)\).

1. Compute the Cholesky factor \(R_X \) of \( \Sigma_X = R_X R_X^T \) that is the stabilizing solution of the projected Riccati equation (16).

2. Compute the eigenvalue decomposition

\[
R_X^T S_{\text{int}} E R_X = [U_1, U_2] \begin{bmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_2 \end{bmatrix} [U_1, U_2]^T,
\]

where \([U_1, U_2]\) is orthogonal, \(\Lambda_1 = \text{diag}(\lambda_1, \ldots, \lambda_r)\) and \(\Lambda_2 = \text{diag}(\lambda_{r+1}, \ldots, \lambda_q)\).

3. Compute the eigenvalue decomposition \((I - M_0) S_{\text{ext}} = U_0 \Lambda_0 U_0^T\), where \(U_0\) is orthogonal and \(\Lambda_0 = \text{diag}(\lambda_1, \ldots, \lambda_m)\).

4. Compute the reduced-order system (18), where

\[
B_{\infty} = S_0 |\Lambda_0|^{1/2} U_0^T S_{\text{ext}}, \quad C_{\infty} = U_0 |\Lambda_0|^{1/2}, \quad S_0 = \text{sign}(\Lambda_0),
\]

\[
W = L U_1 |\Lambda_1|^{-1/2}, \quad T = S_{\text{int}} L U_1 S_1 |\Lambda_1|^{-1/2}, \quad S_1 = \text{sign}(\Lambda_1),
\]

\[
|\Lambda_0| = \text{diag}(|\lambda_1|, \ldots, |\lambda_m|), \quad |\Lambda_1| = \text{diag}(|\lambda_1|, \ldots, |\lambda_1|).
\]

where \(\dot{y}_j = \hat{C}_j \dot{x}_t, j = 1, \ldots, 5\), approximate the corresponding components of the output \(y_t\) in (7a). Therefore, we have

\[
-(A_{R}^2 \bar{R})^T \eta - \eta_z \approx \hat{C}_2 \dot{x}_t, \tag{22a}
\]

\[
-A_{R}^T \eta \approx \hat{C}_3 \dot{x}_t, \tag{22b}
\]

\[
-\iota_{\bar{\mathcal{L}}} \approx \hat{C}_5 \dot{x}_t. \tag{22c}
\]

Then the nonlinear systems (5a) and (6) are approximated by

\[
\hat{C}(\bar{u}_{\bar{z}}) \frac{\partial}{\partial \bar{u}_{\bar{z}}} \bar{u}_{\bar{z}} = -\hat{C}_5 \dot{x}_t \tag{23}
\]

and

\[
\hat{L}(\bar{v}_{\bar{L}}) \frac{\partial}{\partial \bar{v}_{\bar{L}}} \bar{v}_{\bar{L}} = -\hat{C}_3 \dot{x}_t, \tag{24}
\]

respectively. Here, \(\bar{u}_{\bar{z}}\) and \(\bar{v}_{\bar{L}}\) form approximations to \(u_{\bar{z}}\) and \(v_{\bar{L}}\), respectively. Furthermore, for \(\eta_z\) defined in (5b) and \(\iota_z\) defined in (4b), we have

\[
-(A^2_{R} \bar{R})^T \eta - \eta_z = -(A^1_{R} \bar{R})^T \eta - \Gamma^{-1} (G_1 (A^1_{R} \bar{R})^T - G_2 (A^2_{R} \bar{R})^T) \eta + \Gamma^{-1} \iota_z
\]

\[
= -(A^1_{R} \bar{R})^T \eta - \Gamma^{-1} G_1 (A^1_{R} \bar{R} + A^2_{R} \bar{R})^T \eta + (A^2_{R} \bar{R})^T \eta + \Gamma^{-1} \iota_z
\]

\[
= -\Gamma^{-1} G_1 A^1_{R} \bar{R} \eta + \Gamma^{-1} \iota_z
\]

\[
= -\Gamma^{-1} G_1 A^1_{R} \bar{R} \eta + G^{-1}_1 \bar{g}(A^1_{R} \eta) - \Gamma^{-1} G_2 A^2_{R} \bar{R} \eta
\]

\[
= -A^1_{R}^T \eta + G^{-1}_1 \bar{g}(A^1_{R} \eta),
\]

\[
16
\]
Taking into account (22a), the vector $u_\overline{x} = A^T \eta$ can be approximated by $\dot{u}_\overline{x}$ satisfying

$$0 = -G_1 \dot{C}_2 \dot{x}_\ell - G_1 \dot{u}_\overline{x} + \bar{g}(\dot{u}_\overline{x}).$$

(25)

Combining (21), (23), (24), (25) and $i_z \approx \Gamma G_1^{-1}\bar{g}(u_\overline{x}) - G_2 \dot{u}_\overline{x}$, we obtain the DAE system

$$\dot{E} \frac{d}{dt} \dot{x}_\ell = \dot{A} \dot{x}_\ell + \dot{B}_3 \dot{u}_\overline{x} + \dot{B}_5 \dot{u}_\overline{z} - \dot{B}_2 G_2 \dot{u}_\overline{x} + \dot{B}_2 G_1^{-1}\bar{g}(\dot{u}_\overline{x}) + \dot{B}_4 \eta + \dot{B}_4 u_\eta,$$

$$\dot{L} \frac{d}{dt} i_L = \dot{C}_5 \dot{x}_\ell,$$

$$\dot{C} \frac{d}{dt} \dot{u}_\overline{z} = -\dot{C}_5 \dot{x}_\ell,$$

$$0 = -G_1 \dot{C}_2 \dot{x}_\ell - G_1 \dot{u}_\overline{x} + \bar{g}(\dot{u}_\overline{x}).$$

Finally, multiplying the last equation by $-\dot{B}_2 G_1^{-1}$ and adding up the resulting equation to the first one, we obtain the reduced-order nonlinear model

$$\dot{E} \frac{d}{dt} \dot{x} = \dot{A} \dot{x} + \dot{f}(\dot{x}) + \dot{B} u,$$

(26a)

where $\dot{x}^T = [ \dot{x}_\ell^T \ i_L^T \ \dot{u}_\overline{z}^T \ \dot{u}_\overline{x}^T ]$, $u^T = [ u_\eta^T \ u_\eta^T ]$ and

$$\dot{E} = \begin{bmatrix} E & 0 & 0 & 0 \\ 0 & \dot{L}(i_L) & 0 & 0 \\ 0 & 0 & \dot{C}(\dot{u}_\overline{z}) & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad \dot{A} = \begin{bmatrix} \dot{A} + \dot{B}_2 \dot{C}_2 \dot{B}_3 \dot{B}_5 \dot{B}_2 G_1 \\ -\dot{C}_3 & 0 & 0 & 0 \\ -\dot{C}_5 & 0 & 0 & 0 \\ -G_1 \dot{C}_2 & 0 & 0 & -G_1 \end{bmatrix},$$

$$\dot{f}(\dot{x}) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ \bar{g}(\dot{u}_\overline{x}) \end{bmatrix}, \quad \dot{B} = \begin{bmatrix} \dot{B}_1 & \dot{B}_4 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad \dot{C} = \begin{bmatrix} \dot{C}_1 & 0 & 0 & 0 \\ \dot{C}_4 & 0 & 0 & 0 \end{bmatrix}.\quad (26b)$$

This model represents a nonlinear approximation to the nonlinear DAE system (1). It can now be used for further investigations in steady-state analysis, transient analysis or sensitivity analysis of electronic circuits. Note that the error bounds (19), (20) for the reduced-order linear subsystem (21) can be used to estimate the error in the output of the reduced-order nonlinear system (26), see [9] for such estimates for a special class of nonlinear circuits. Error bounds for general circuits remain for future work.

4 Numerical Experiments

In this section, we present some results of numerical experiments for two different nonlinear circuits. The computations were done with MATLAB.
Example 4.1 First, we consider a nonlinear circuit shown in Figure 5. It contains 1501 linear capacitors, 1500 linear resistors, 1 voltage source and 1 diode. Such a circuit is described by the DAE system (1) of the state space dimension \( n = 1503 \). We simulate this system on the time interval \( \mathcal{I} = [0s, 0.07s] \) with a fixed stepsize \( 10^{-5}s \) using the BDF method of order 2. The voltage source is given by \( u_y(t) = 10 \sin(100\pi t)^4 V \), see Figure 6. The linear resistors have the same resistance \( R = 2 \, k\Omega \), the linear capacitors have the same capacitance \( C = 0.02 \, \mu \text{F} \) and the diode has a characteristic curve \( g(u) = 10^{-14}(\exp(40 \frac{1}{\sqrt{v}}u) - 1) \, A \).

![Figure 5: Nonlinear RC circuit](image)

![Figure 6: Voltage source for the RC circuit](image)

The dimension \( r_\ell \) of the reduced-order linear system (15) was determined as \( r_\ell = r + r_0 \), where \( r_0 = \text{rank}(I - M_0) \) and \( r \) satisfies the condition \( (\pi_{r+1} + \ldots + \pi_q) < \text{tol} \) with a prescribed tolerance \( \text{tol} \). For comparison, we compute the reduced-order linear models for the different tolerances \( \text{tol} = 10^{-2}, 10^{-3}, 10^{-4}, 10^{-5} \). The numerical results are given in Figure 7. In the upper plot of each subfigure, we present the computed outputs \( y(t) = -t_y(t) \) and \( \hat{y}(t) \) of the original and reduced-order nonlinear systems, respectively, whereas the lower plot shows the error \( |y(t) - \hat{y}(t)| \).

Table 1 demonstrates the efficiency of the proposed model reduction method. One can see that for the decreasing tolerance, the dimension of the reduced-order system increases while the error in the output decreases. The speedup is defined as the simulation time for the original system divided by the simulation time for the reduced-order model. For example, a speedup of 219 in simulation of the reduced-order model of dimension \( \hat{n} = 13 \) with the error \( \| y - \hat{y} \|_{L_2(\mathcal{I})} = 6.2 \cdot 10^{-7} \) was achieved compared to the simulation of the original system.
Figure 7: Outputs of the original and the reduced-order nonlinear systems and the errors in the output for the different tolerances a) $10^{-2}$, b) $10^{-3}$, c) $10^{-4}$, d) $10^{-5}$.

| dimension of the original nonlinear system, $n$ | 1503 | 1503 | 1503 | 1503 |
| simulation time for the original system, $t_{sim}$ | 2401.2s | 2401.2s | 2401.2s | 2401.2s |
| tolerance for model reduction of the linear subsystem, $tol$ | 1e-02 | 1e-03 | 1e-04 | 1e-05 |
| time for model reduction, $t_{mor}$ | 15s | 24s | 42s | 61s |
| dimension of the reduced nonlinear system, $\hat{n}$ | 10 | 13 | 16 | 19 |
| simulation time for the reduced system, $t_{\hat{sim}}$ | 82s | 110s | 122s | 155s |
| error in the output, $\|\hat{y} - y\|_{L_2(\Omega)}$ | 7.0e-06 | 6.2e-07 | 2.0e-07 | 4.2e-07 |
| speedup, $t_{sim}/t_{\hat{sim}}$ | 294.0 | 219.0 | 197.4 | 155.0 |

Table 1: Statistics for the RC circuit
**Example 4.2** We consider now the nonlinear circuit shown in Figure 8. It contains 1000 repetitions of subcircuits consisting of 1 inductor, 2 capacitors and 2 resistors. Furthermore, at the beginning and at the end of the chain, we have a voltage source with \( u_x(t) = \sin(100\pi t) \text{V} \) as in Figure 9 and an additional linear inductor, respectively. In the 1st, 101st, 201st, etc., subcircuits, a linear resistor is replaced by a diode, and in the 100th, 200th, 300th, etc., subcircuits, a linear inductor is replaced by a nonlinear inductor. The resulting nonlinear circuit contains 1 voltage source, 1990 linear resistors with \( R_1 = 20\Omega \text{ and } R_2 = 1\Omega \), 991 linear inductors with \( L = 0.01\text{H} \), 2000 linear capacitors with \( C = 1\mu\text{F} \), 10 diodes with \( g(u_x) = 10^{-14}(\exp(40u_x) - 1)\text{A} \), and 10 nonlinear inductors with

\[
\mathcal{L}(t_x) = L_{\text{min}} + (L_{\text{max}} - L_{\text{min}}) \exp(-t_x^2 L_{\text{decl}}),
\]

where \( L_{\text{min}} = 0.001\text{H} \), \( L_{\text{max}} = 0.002\text{H} \) and \( L_{\text{decl}} = 10^{41}/K \). The state space dimension of the resulting DAE system is \( n = 4003 \).

**Figure 8: Nonlinear RLC circuit**

The numerical simulation is done on the time interval \( \mathbb{I} = [0, 0.05s] \) using the BDF method of order 2 with a fixed stepsize of length \( 5 \cdot 10^{-3}s \). In Figure 10, we again present the outputs \( y(t) = -x_x(t) \) and \( \dot{y}(t) \) of the original and reduced-order nonlinear systems, respectively, as well as the error \( |\dot{y}(t) - y(t)| \) for the different tolerances \( \text{tol} = 10^{-2}, 10^{-3}, 10^{-4}, 10^{-5} \) for model reduction of the decoupled linear subcircuit. Table 2 demonstrates the efficiency of the model reduction method. As in the example above, also here one can see that if the
tolerance decreases, the dimension of the reduced-order system increases while the error in the output becomes smaller. In particular, for the approximate model of dimension $\hat{n} = 189$ with the error $\|y - \hat{y}\|_2 = 4.10 \cdot 10^{-5}$, the simulation time is only 57 seconds instead of 1 hour and 13 minutes for the original system that implies a speedup of 76.8.

Figure 10: The outputs of the original and the reduced-order nonlinear systems and the errors in the output for the different tolerances a) $10^{-2}$, b) $10^{-3}$, c) $10^{-4}$, d) $10^{-5}$.

5 Conclusion

In this paper, we developed a model order reduction method for large-scale nonlinear DAE systems arising in circuit simulation. This method is based on decoupling the electronic circuit into linear and nonlinear subcircuits followed by model reduction of the linear

part using a passivity-preserving balancing-related technique. Afterwards, the reduced-order linear model is recoupled with the unchanged nonlinear subsystem to obtain the reduced-order nonlinear model. We also analyzed the decoupling effects on the properties of the extracted linear subsystem. The efficiency and applicability of the considered model reduction approach was demonstrated on two numerical examples.
